

Integrated Electrochemical Systems for Scalable CO₂ Conversion to Chemical Feedstocks

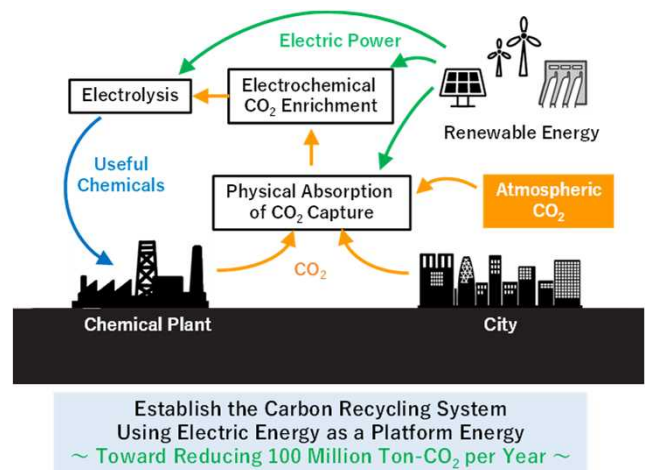

Project Manager (PM) : SUGIYAMA Masakazu, The University of Tokyo

Summary

We will develop an integrated system that recovers and enriches dilute CO₂ from the atmosphere using physical and electrochemical methods and converts it to a resource utilizing an electrochemical process powered by renewable energy.

Targeting dilute CO₂ in the atmosphere as an ultimate goal, we will establish a flexible and scalable system that is distinct from thermochemical plants, which can be distributed on a small scale by taking advantage of the characteristics of electrochemical processes. This will create a technology that can be applied to a wide range of CO₂ emissions sources, from indoor air in buildings to factory exhaust.

The integrated system consists of two main technologies: CO₂ capture and enrichment by both physical and electrochemical methods, and CO₂ reduction to produce useful chemical feedstock (e.g., ethylene). In particular, we will develop core technologies for CO₂ separation and enrichment through electrochemical CO₂ dissolution control and highly efficient and highly selective CO₂ electrochemical reduction through innovative catalysts and reactors. We will integrate these technologies into a unified process and promote plant demonstrations with the aim of socially implementing an innovative CO₂ conversion system to resources.

KPI

FY2022

Develop/verify devices to demonstrate that CO₂ emissions can be reduced to between +1.0 and +1.5 tons per ton of ethylene produced. (Note 1, Reference)

FY2024

Examine the feasibility of a laboratory-scale system and demonstrate that CO₂ emissions can be reduced to between +0.5 and +1.0 tons per ton of ethylene produced, and that continuous operation for 1000 hours can be achieved.

FY2029

A pilot plant will be constructed to achieve carbon negativity, i.e., CO₂ emissions of less than -0.5 tons per ton of ethylene produced. Also, achieve 5000 hours of continuous operation.

Note 1) Includes CO₂ emissions during equipment manufacturing (estimated based on technology as of July 2021).

(Reference) Conventional technologies that use fossil resources as raw materials emit several tons of CO₂ per ton of ethylene produced.

Implementation

The University of Tokyo, Osaka University, Institute of Physical and Chemical Research (RIKEN), Ube Industries, Ltd., Shimizu Corporation, Chiyoda Corporation, Furukawa Electric Co., Ltd.
